in computer and information science, Vol. 9(2004): nr 12.  
<http://www.ep.liu.se/ea/cis/2004/12/>. September 24, 2004.*

*This URL will also contain a link to the author's home page.*

*The publishers will keep this article on-line on the Internet  
(or its possible replacement network in the future)  
for a period of 25 years from the date of publication,  
barring exceptional circumstances as described separately.*

*The on-line availability of the article implies  
a permanent permission for anyone to read the article on-line,  
to print out single copies of it, and to use it unchanged  
for any non-commercial research and educational purpose,  
including making copies for classroom use.  
This permission can not be revoked by subsequent  
transfers of copyright. All other uses of the article are  
conditional on the consent of the copyright owner.*

*The publication of the article on the date stated above  
included also the production of a limited number of copies  
on paper, which were archived in Swedish university libraries  
like all other written works published in Sweden.  
The publisher has taken technical and administrative measures  
to assure that the on-line version of the article will be  
permanently accessible using the URL stated above,  
unchanged, and permanently equal to the archived printed copies  
at least until the expiration of the publication period.*

Electronic Press and its procedures for publication and for  
assurance of document integrity, please refer to  
its WWW home page: <http://www.ep.liu.se/>  
or by conventional mail to the address stated above.*

## Abstract

The paper analyzes and compares methods for ramification, or for update, which are based on minimization of change while respecting static domain constraints. The main results are:

- An underlying semantics for propagation oriented ramification, called *causal propagation semantics*
- *Comparative assessments* of a number of previously proposed entailment methods for ramification, in particular, methods based on minimization of change after partitioning of the state variables (fluents). This includes the methods previously proposed by del Val and Shoham, by Kartha and Lifschitz, and by our group.
- Assessment of two *ranges of sound applicability* for one of those entailment methods, MSCC, relative to causal propagation semantics.
- Identification of an essential feature for minimization-based approaches to ramification, namely *changeset-partitioning*.

# 1 Topic and approach

## 1.1 The ramification problem

The *ramification problem* for reasoning about actions and change has been described as follows by Ginsberg and Smith, [?]:

The difficulty is that it is unreasonable to explicitly record all of the consequences of an action, even the immediate ones. For example [...] For any given action there are essentially an infinite number of possible consequences that depend upon the details of the situation in which the action occurs.

More concretely, the difference between ramification and the simpler case of strict inertia is that strict inertia assumes action laws to specify *all* the effects of the action explicitly, whereas in ramification the action law only needs to specify *some of* the effects; the others are to be deduced. On the other hand, the logic cannot do magic; those other effects must also be declared somehow. One can think of two specific reasons why ramification is useful:

1. In order to avoid duplication of the same information on the consequent side of several action laws. Suppose, for a trivial example, that both *alive(x)* and *dead(x)* occur as state variables. Under strict inertia, every action that causes a change in *alive(x)* must also specify the corresponding change in *dead(x)*.
2. In order to avoid configuration-dependent action laws. Suppose the scenario world consists of a number of interconnected objects, where a change in one of them may cause changes in neighboring objects, and different scenarios in the same world contain different configurations. If the same action law is going to be used in all scenarios, it must apply regardless of the choice of configuration, and then it is not possible to represent the secondary changes explicitly in the action law.

We shall refer to these as the *redundancy* reason and the *propagation* reason for ramification, respectively.
